

Base station battery pack single cell voltage is high

51.2V 150AH, 7.68KWH

Overview

Most cases of a cell voltage showing incorrectly when the pack is not under load or charge are a result of wiring an loose or disconnected cell tap wire or a result of damage to the BMS unit from altering battery pack wiring while the BMS is connected. As EV battery systems continue to shift toward higher voltages, ensuring safe and efficient measurement becomes increasingly important. This article outlines the key considerations for accurately monitoring voltage and temperature in high-voltage battery packs, helping to support safer and more. Cell imbalance in a high-voltage (HV) battery pack might not throw a red flag right away, but it's often the canary in the coal mine for long-term health issues. This discrepancy can compromise the battery's overall performance and safety. The means used to perform cell balancing typically include by-passing some of the cells during charge (and sometimes during discharge) by connecting external loads. If individual cells within the battery pack have different internal resistances or different overall capacities or have never been top (or bottom, usually top for solar applications) balanced or weren't of the same State of charge when built then they can have differences in their balance/level of.

This document is intended to assist in diagnosing voltage readings that are incorrect while the battery pack is at rest (no current entering or leaving the battery pack) only.

Symptoms of unbalanced batteries

Best way to spot if a pack is unbalanced is to check the BMS. Most BMS will have an app or screen that lets you monitor the voltage of each cell which will make it easy to see how out of ...

[Best balancing strategy for an old pack with one weak cell](#)

One cell is weaker than the rest - it's the first to hit the high-voltage cutoff on charge, and the first to hit low-voltage cutoff on discharge. I'd estimate its capacity as maybe 30Ah.

Battery Cell Balancing: What to Balance and How

As result, the open circuit voltage of this cell at the end of charge will be different from the other cells and can reach high levels, potentially causing the safety circuit to trip.

One cell level too high

You could discharge the one cell with a power resistor or automotive headlight bulb. That works quite well to bleed power from a high cell.
