

# Communication base station power supply voltage standard

## Overview

---

Over time, 48V became the standardized nominal voltage. To further enhance safety and interference resistance, engineers adopted a negative-ground system, where: The negative pole is grounded The positive pole operates at -48V relative to ground. Power factor corrected (PFC) AC/DC power supplies with load sharing and redundancy (N+1) at the front-end feed dense, high efficiency DC/DC modules and point-of-load converters on the back-end. A power efficient design is required that supplies both the higher voltage analog circuits and multiple. They must provide stable voltage, protect against power surges, and offer backup solutions during outages. These systems often include components such as rectifiers, inverters, and batteries. Modern FPGAs and processors are built using advanced nanometer processes because they often perform calculations at fast speeds using low voltages (<0.9 V) at high current from compact. At the time, engineers needed a voltage level that could: Support long-distance power transmission with acceptable voltage drop Reliably operate electromechanical relays and telephone circuits Enable ringing signals without excessive complexity Around 50V DC proved to be the optimal solution. Because the smallest communication network and communication engineering are all.
